

## Python code for One dimensional heat equation

```
#we will first transform the one dimensional heat equation using the finite difference for
#then we impose start and end boundary condition values on the equaion
#finally we plot the changes in temperature per distance
```

```
#Note
```

```
#(1) that we are told to heat the bar to a fixed positive temperatures at both ends
#this will be given by setting the left and right boundary conditions to a positive values
#left boundary condition =20
#right boundary condition=40
```

```
#(2) we need to also set the initial condition to a non-trivial temperature distribution-t
#temperature to a non-zero (non-trivial) => u(0,x)=f(x) = with 5degrees value -in our case
```

```
#(3) we need to set the heat flux approximation in the finite difference scheme
#this we will approximate it as follows
#Note in the code below==heat flux approximation in finite difference scheme will be denot
```

$$\Rightarrow \text{heat flux defined : } \vec{q} = -k\nabla U / \Delta x$$

$$\Rightarrow \rho c_p \Delta x \frac{dU}{dt} \approx \frac{-k\nabla U(\nabla)}{\Delta x}$$

$\Rightarrow$  In finite difference we have :

$$\Rightarrow \frac{dU}{dt} = \frac{k}{\rho c_p} \left( \frac{U_{i-1} + U_{i+1} - 2U_i}{\Delta x^2} \right)$$

$\Rightarrow$  We approximate the heat flux in finite difference as :

$$\Rightarrow \frac{dU}{dt} = \alpha \left( \frac{U_{i-1} + U_{i+1} - 2U_i}{\Delta x^2} \right)$$

$$\Rightarrow \alpha = \frac{k}{\rho c_p} = 0.0001$$

```
#importing important libraries
import numpy as np
import matplotlib.pyplot as plt
import warnings
warnings.filterwarnings("ignore")

#setting a random alpha value for the heat equation
cons =0.0001 # (alpha) #NOTE ,this can be changed accordingly based on the heat equation

s=5 # x number of steps
T0=5 # setting initial condition temperature to start from zero (non trival value 5degrees

L=0.1 # critical length value
dx=L/s # change in step length
final temp=100 #setting final temperature
```

```

dt=0.1 # time step

t=np.arange(0,final_temp,dt)
x=np.linspace(dx/2,L-dx/2,s) # setting x in the specified interval

T=np.ones(s)*T0 #converting initial Temp condition from scalar to vector
U=np.empty(s) #derivative initialization

left_boundary_condition=int(input('Enter temperature at left end: ')) # left boundary cor
right_boundary_condition=int(input('Enter temperature at right end: ')) # right boundary

for _ in range(1,len(t)):
    for k in range(1,s-1):

        #the finite difference transformation of the one dimensional heat Pde equation
        U[k]=((T[k+1]-T[k])/dx**2-(T[k]-T[k-1])/dx**2)*cons

        #applying the set boundary conditions
        U[s-1]=((right_boundary_condition-T[s-1])/dx**2-(T[s-1]-T[s-2])/dx**2)*cons
        U[0]=((T[1]-T[0])/dx**2-(T[0]-left_boundary_condition)/dx**2)*cons

#plotting the results
T+=U*dt
plt.semilogy(x,T)
plt.title('Temperature change in distance L')
plt.ylabel('Temperature')
plt.xlabel('Length')
# plt.legend()

```

Enter temperature at left end: 20  
Enter temperature at right end: 40
